If instead we apply the Laplace transform to this, applying the Laplace transform is the same as taking the Fourier transform of x of t times an exponential, and the exponent that we would multiply by is $e^{-\sigma t}$. So in effect, taking the Laplace transform of this is like taking the

Lecture 20: The Laplace Transform - MIT OpenCourseWare

The Laplace transform is a function of a general complex variable s , and for any given signal the Laplace transform converges for a range of values of s . 20-1 Signals and Systems 20-2 This range is referred to as the region of convergence (ROC) and plays an important role in specifying the Laplace transform associated with a given signal.

Laplace Transform: Definition. Laplace transform maps a function of time t to a function of s . $X(s) = \int_{-\infty}^{\infty} x(t) e^{-st} dt$. There are two important variants: Unilateral (18.03) $X(s) = \int_0^{\infty} x(t) e^{-st} dt$. Bilateral (6.003) $X(s) = \int_{-\infty}^{\infty} x(t) e^{-st} dt$. Both share important properties. We will focus on bilateral version, and discuss di

Use the Laplace transform to solve the differential equation $x'' + x = \sin(t)$, with $x(0) = 0$, $x'(0) = 0$. (Hint: use the table to do the Laplace inverse.) The zero initial conditions make taking the Laplace transform of the differential equation easy $(s^2 + 1)X(s) = \frac{1}{s^2 + 1}$: This is in our Laplace table. So, $x(t) = \frac{1}{2} (\sin(t) - t \cos(t))$:
