Finite Difference Method for Solving Differential Equations

The first step is to partition the domain [0,1] into a number of sub-domains or intervals of length h. So, if the number of intervals is equal to n, then $nh = 1$. We denote by x_i the interval end points or nodes, with $x_1 = 0$ and $x_{n+1} = 1$. In general, we have $x_i = (i - 1) h$.

Finite Difference Methods for Boundary Value Problems

A finite difference is a mathematical expression of the form $f(x + b) - f(x + a)$. If a finite difference is divided by $b - a$, one gets a difference quotient. The approximation of derivatives by finite differences plays a central role in finite difference methods for the numerical solution of differential equations, especially boundary value problems.
