Mandibular fracture, also known as fracture of the jaw, is a break through the mandibular bone. In about 60% of cases the break occurs in two places. It may result in a decreased ability to fully open the mouth. Often the teeth will not feel properly aligned or there may be bleeding of the gums.

Mandibular fractures occur most commonly among males in their 30s. Mandibular fractures are typically the result of trauma. This can include a fall onto the chin or a hit from the side.

Mandibular Fractures. Common Mandibular Fractures | Patient
A mandible fracture is similar to a bone fracture in any another area of the body. The bone becomes stressed, usually from excessive force, and breaks under that pressure. The first step in the diagnosis is taking a dental X-ray (also known as a radiograph) to measure the presence and severity of the crack, split or complete break.

This Second Edition includes full-color intraoperative photographs that complement the surgical drawings. Several new approaches have been added—the transconjunctival approach to the medial orbit, subtarsal approach to the internal orbit, Weber-Ferguson approach to the midface, and facial degloving approach to the midface.
