Molecular Basis of Inheritance - Regulation of Gene Expression Gene Expression In Prokaryotes Pogil

The regulation of gene expression in prokaryotic cells occurs at the transcriptional level. There are two major kinds of proteins that control prokaryotic transcription: repressors and activators.

Repressors bind to an operator region to block the action of RNA polymerase. Activators bind to the promoter to enhance the binding of RNA polymerase.

Likewise, prokaryotic cells can turn genes on and off based on environmental factors. Sometimes related genes are grouped together with one switch. This group of genes, along with the sections of DNA that regulate them, is called an operon.

The regulation of gene expression in prokaryotic cells occurs at the transcriptional level. Simply stated, if a cell does not transcribe the DNA's message into mRNA, translation (protein synthesis), does not occur. Bacterial genes are often organized into common pathways or processes called operons for more coordinated regulation of expression.

Prokaryotes regulate gene expression (and therefore their metabolism) almost entirely by regulating transcription. The lack of a nucleus makes this very efficient. Eukaryotes regulate gene expression (and therefore their metabolism) at every step of protein synthesis from pre-transcription to post-translation.
