The natural frequencies and mode shapes are arguably the single most important property of any mechanical system. This is because, as we shall see, the natural frequencies coincide (almost) with the system 's resonant frequencies. That is to say, if you apply a time varying force to the system, and choose the frequency of the force to be equal to one of the natural frequencies ...

When a mechanical system is responding purely at one natural frequency in the steady state, its deflection pattern will have a unique shape called the mode shape or eigenvector. Mode shapes are normalized and frequently to a maximum value of 1, but in reality the maximum value selected is arbitrary. Only the shapes have significance. This is because the system is unforced and so the mode shapes define only the deflection patterns for which the inertia and stiffness forces are completely in ...

Mode Shape Reduction Every beam, of any length, has one natural frequency for each wave (mode) it can generateand it can only generate an exact number (integer) of waves between its supportsthat is, it can generate 1 wave (2 nodes), 2 waves (3 nodes), 3 waves (4 nodes), etc.but it cannot generate a non-integer number of waves; 1.25, 2.47, 6.1, etc.

A normal mode of an oscillating system is a pattern of motion in which all parts of the system move sinusoidally with the same frequency and with a fixed phase relation. The free motion described by the normal modes takes place at fixed frequencies. These fixed frequencies of the normal modes of a system are known as its natural frequencies or resonant frequencies. A physical object, such as a building, bridge, or molecule, has a set of normal modes and their natural frequencies that depend on i

These special initial deflections are called mode shapes, and the corresponding frequencies of vibration are called natural frequencies. The natural frequencies of a vibrating system are its most important property. It is helpful to have a simple way to calculate them.

These rates of vibration are called natural frequencies. Associated with each of these rates of vibration is a shape of the structure called the mode shape. Every system's vibration behavior can be characterized by computing these natural frequencies and mode shape associated with them.

We compute the natural frequencies and mode shapes of a filter composed of two clamped-clamped microbeam resonators (primary beams) coupled by a microbeam, as shown in Figure 1(a). Each primary resonator is divided into two parts at the location, where the coupling beam is attached to it, as shown in Figure 1(b). Consequently, the boundary-value problem (BVP) governing the natural frequencies and mode shapes is composed of five equations (one equation for each part of the primary beams and ...
