X-ray crystallography is a powerful non-destructive technique for determining the molecular structure of a crystal. X-ray crystallography uses the principles of X-ray diffraction to analyze the sample, but it is done in many different directions so that the 3D structure can be built up. It is a technique that has helped to deduce the 3D crystal structure of many materials, especially biological materials.

Beam Width. • The beam width (FWHM) is given by the Scherrer Law:  $B(2\theta) = K \lambda / (N a \cos \theta)$  •  $K$ -shape factor •  $N$  - size of the crystal in unit cells •  $a$  - unit cell length for a square crystal •  $\lambda$  - Wavelength •  $\theta$  - Bragg angle. Verification. • The Scherrer law is verified in two ways.

X-ray crystallography is a tool used for determining the atomic and molecular structure of a crystal. The underlying principle is that the crystalline atoms cause a beam of X-rays to diffract into many specific directions (Fig. 2.10). By measuring the angles and intensities of these diffracted beams, a crystallographer can produce a 3D picture of the density of electrons within the crystal.

In crystallography, many of the optical or X-ray measurements lead in the first instance to the b-axes. A lattice vector in the reciprocal lattice is defined as the vector from the origin to any other lattice point. Thus it is  $\mathbf{h} = h_1 \mathbf{b}_1 + h_2 \mathbf{b}_2 + h_3 \mathbf{b}_3$ , (10) in analogy to Eq. (5) for the lattice vector in the crystal lattice.

Principle - When an X-ray bean is passed through a substance, the electrons of its atoms emit electromagnetic radiation in all directions like that of the incident X-radiation. These scattered waves from the electrons are arranged in the form of the crystal lattice. The interference of these waves causes diffraction by the crystal plane.
