Lecture 13 Phonons: thermal properties

The most fundamental thermal properties of solids can be determined from the phonon dispersion q, v (for wave vector q of the v th mode) and the corresponding phonon density of states (DOS) as a function of frequency. The Helmholtz free energy at the temperature T and for a constant volume V is given by $F(T, V) = -k_B T \ln \Omega(T, V)$

Thermal properties of bulk zinc-blende boron arsenide (BAs) were investigated by performing ab initio calculations using both the local density approximation (LDA) and generalized gradient approximation (GGA) for the exchange-correlation potential. Phonon dispersion relations were studied within the framework of density functional perturbation theory (DFPT) and the subsequent thermal properties were computed using the quasi-harmonic approximation (QHA).

The entire set of all possible phonons that are described by the phonon dispersion relations combine in what is known as the phonon density of states which determines the heat capacity of a crystal. By the nature of this distribution, the heat capacity is dominated by the high-frequency part of the distribution, while thermal conductivity is primarily the result of the low-frequency region.

The phonon band structures and the partial density of states are also investigated, and we find that both CsBi₄Te₆ and Bi₂Te₃ exhibit localized phonon states at low frequencies. At high temperatures, the decrease of the volume expansion with temperature indicates the potential of a good thermal conductivity in this temperature region.

Thermal properties in the harmonic approximation ¶ . This section of the tutorial demonstrates how an existing FCP can be employed in conjunction with phonopy to analyze the thermal properties of a material in the harmonic approximation.. Note that this analysis by definition invokes only the second-order force constants and primarily relies on phonopy.
